

The Philosophy of Causal Proxy Segregation

(How Subjective Truth Becomes Computationally Faithful)

1. The Foundational Premise

Every Experience Driver may host **multiple subjective realities** expressed through different customer voices.

To preserve authenticity, the architecture treats each feedback instance not as statistical noise but as a **signal of intent, emotion, and causality**. Meaning must never be averaged before it is understood.

Hence, the system's first duty is **ethical separation** to distinguish between distinct causes of sentiment before any aggregation occurs.

2. From Feedback to Meaning: The Four-Layer Logic

Layer	Functional Essence	Philosophical Role
Experience Driver (ED)	The object of experience — what the customer is referencing.	Defines <i>the world being spoken about</i> .
Feedback Type (FT)	The communicative mode — complaint, compliment, request, etc.	Defines <i>the human intent</i> .
Opportunity Stream (OS)	The direction of change — fix, optimize, amplify, innovate.	Defines <i>the action purpose</i> .
Causal Proxy (CP)	The diagnostic unit — clusters of similar causes or talking points.	Defines <i>the moral why</i> .

When ED×FT×OS yields a single mention, that instance itself becomes the **Single Source of Truth (SSoT)**.

When it yields many mentions, the system invokes the **Causal Proxy Segregator**: a reasoning layer that groups instances by similarity of cause rather than by surface vocabulary.

This preserves *interpretive integrity* while enabling computational manageability.

3. The Moral Economy of Representation

Each resulting cluster is considered a **moral unit of meaning**; a space where multiple human experiences converge around one behavioral truth.

When cluster coherence exceeds a human-grade fidelity threshold ($\approx 90\%$), the system declares that cluster as an SSoT:

The minimal viable unit of shared human meaning on that topic.

From that point onward, orchestration units and PDCA cycles act upon that SSoT, ensuring the enterprise intervenes at the level of *understood truth*, not *statistical illusion*.

4. The Role of Pareto as Cognitive Heuristic

The 80/20 rule within each layer is not a mechanical filter but a **cognitive safeguard**.

It reflects how human attention naturally focuses on dominant patterns without muting rare but high-impact voices.

Thus, Pareto is reinterpreted as *bounded rationality applied to empathy*, a discipline of listening deeply but efficiently.

5. The Purpose of the Medoid Principle

When multiple instances exist within a Causal Proxy cluster, the architecture chooses the **medoid** — the instance most representative of the cluster's shared meaning.

This ensures that the chosen SSoT embodies the centroid of human sentiment rather than an arbitrary example. It is not an average; it is the *most truthful exemplar*.

6. Philosophical Consequence: Integrity Before Intelligence

The architecture is deliberately designed to privilege **integrity over precision**. Computation follows comprehension; quantification follows qualification.

Only after subjective truths are faithfully segregated does the system allow automation, scoring, or prediction.

This sequence guarantees that **empathy is structurally encoded**, not post-rationalized.

7. Outcome: A Scalable Ethics of Understanding

Through Causal Proxy Segregation, the architecture achieves a scalable form of moral reasoning:

- Every signal is heard in context.
- Similar experiences converge without distortion.
- Each cluster becomes an actionable narrative rather than a datapoint.
- Emotion becomes **programmable infrastructure** grounded in human integrity.

This philosophical base allows Decipher - and any SAA-compliant system - to transform raw sentiment into structured truth, preserving empathy at enterprise scale.
