

Imposing Relational Structure on Experience Drivers - Emotionally Weighted

The Question That Defined a Category

December 2025

The Central Question

How do you impose relational structure on the drivers of human experience - emotionally weighted?

This question had never been properly answered in the history of computing.

Until now.

Why This Question Matters

The Problem Space

For over 50 years, organizations have collected emotional signals:

- Customer feedback
- Support tickets
- Survey responses
- Social media mentions
- Employee sentiment
- Patient experiences

But while emotion was captured, **the determinants of experience were not structured.**

Every analysis started from scratch.

Themes drifted.

Issues had no permanent identity.

There was no memory of what worked before.
No causality between actions and outcomes.

The result:

- Experience determinants existed as commentary, not computation
 - Emotion existed as noise, not as a usable signal
-

The Failure of Previous Approaches

What others built:

- **Sentiment Analysis** — scores emotion but creates no structure
- **Theme Clustering** — groups language, but themes drift
- **NPS / CSAT** — measures perception, not causality
- **Text Analytics** — extracts patterns without schema or lineage

The core deficiency:

None of these approaches treat **Experience Drivers** as data that require a relational model.

They treat experience-related feedback as:

- Unstructured text to be analyzed
- Aggregate scores to be tracked
- Themes to be reported

But never as:

- Entities with permanent identity
- States with temporal evolution
- Relationships with referential integrity
- Histories with causal lineage

Emotion was treated as either:

- Decoration (dashboard color)
- Noise (to be filtered out)

Never as:

- **A weighting signal acting on structured driver state**
-

Why Experience Drivers Do Not Drift

Traditional “themes” drift because they are linguistic summaries of text. They depend on phrasing, synonyms, and analyst interpretation.

Experience Drivers do not drift because they represent **system-caused determinants**.

They remain stable because:

- They describe underlying operational causes, not wording
- They map to consistent real-world mechanics (e.g., Refund Cycle Time, Slot Availability)
- They are grounded in semantic constraints and normalization
- They persist even when language changes

An Experience Driver is **not a label**. It is a **computational entity with referential integrity**.

The Breakthrough: The Emotional Relational Model (ERM)

The Core Insight

Experience Drivers are data.

Emotion is signal.

Data requires structure.

Structure enables computation.

To make Experience Drivers computable — emotionally weighted — the same rigor Codd imposed on data must be applied:

- Define entities
- Enforce relationships
- Maintain invariants
- Preserve lineage
- Enable queries

Emotion does **not** become the object of computation. Emotion becomes the **force acting on the object**.

The object is the **Experience Driver**. The state of that object is the **SEU**.

The Three Laws of the ERM

Law 1: Identity Law

Each Experience Driver has exactly one canonical SEU per analysis window.

This means:

- Every driver has a permanent identity
 - No duplicate states
 - No parallel interpretations
 - One source of truth per driver per timeframe
-

Law 2: Lineage Law

Every OU activation is a timestamped state transition linked to a SEU, carrying outcome and consequence.

This means:

- Every action is immutably tied to the driver state that triggered it
 - Every outcome traces back to a specific condition
 - The causal chain is preserved
-

Law 3: Memory Law

Every Experience Driver state transition retains referential integrity across time.

This means:

- No driver state is ever orphaned
 - Historical outcomes constrain future decisions
 - The system can query its own biography
-

From Laws to Structure: The Schema

Core Entities (Conceptual)

1. **Experience Drivers:** Permanent, canonical identities for system-level determinants of experience

2. **Structured Experience Units (SEUs):** The emotionally weighted state of an Experience Driver over time
 3. **Mentions:** Raw evidence linked to drivers and aggregated into SEUs
 4. **Orchestration Units (OUs):** Behavioral missions derived from clustered mentions
 5. **OU Activations:** Executed instances of missions
 6. **Problem Statements:** PDCA-ready articulation of what must be solved
 7. **PDCA Cycles:** Structured execution loops
 8. **Outcome Evaluations:** Proof of before/after driver-state change
 9. **Institutional Memory Events (IME):** Lineage records of all transitions, silences, and patterns
-

Why SEUs Represent State — Not Insight

An SEU is **not** an interpretation or summary.

It is:

- Deterministic
- Queryable
- Stable across agents and time

It represents the **current condition of an Experience Driver**, emotionally weighted.

Agents cannot operate on themes. They **can** operate on SEUs.

Emotion does not define the SEU. Emotion **weights** it.

The ERM Lifecycle (Conceptual)

Raw Mention

↓

Experience Driver (identity)

↓

SEU (driver state, emotionally weighted)

↓

OU (mission)
↓
OU Activation (action)
↓
PDCA Cycle (execution)
↓
Outcome Evaluation (truth)
↓
IME (memory)
↓
Next SEU (updated driver state)

The Execution Loop: PDAM

Perceive → Decide → Act → Memory

This is not a workflow. It is a **stored procedure over the ERM schema**.

Why This Is Foundational

What ERM Enables

Before ERM

- No persistent driver identity
- No provable outcomes
- No shared state for agents
- No institutional memory

After ERM

- Experience Driver state becomes queryable
 - Actions have verifiable impact
 - Agents coordinate on shared truth
 - Learning compounds over time
-

Why LLMs Alone Can Never Do This

LLMs can interpret emotion. They **cannot govern Experience Drivers**.

They cannot:

- Impose canonical identity
- Enforce lineage
- Maintain referential integrity
- Guarantee deterministic state
- Act as a multi-agent truth layer

ERM can.

The Answer

How do you impose relational structure on Experience Drivers — emotionally weighted?

You:

1. Define permanent identities (Experience Drivers)
2. Track state over time (SEUs)
3. Link actions to states (OUs + Activations)
4. Verify outcomes (Outcome Evaluations)
5. Preserve lineage (IME)
6. Enforce invariants (Three Laws)
7. Maintain referential integrity (Schema constraints)

That is the Emotional Relational Model.

Final Statement

Experience Drivers are no longer soft abstractions.
They are structural.

They have:

- identity
- state
- lineage
- causality
- memory

Emotion is no longer decoration.

Emotion is signal — a weighting force acting on structured driver state.

This is infrastructure-level work.

The category is defined.

The primitive is clear.

The question is answered.
